

Metal Industry Indicators

Indicators of Domestic Primary Metals, Steel, Aluminum, and Copper Activity

April 2010

The primary metals leading index surged in March, resuming its upward climb that began last year. The leading index's 6-month smoothed growth rate rebounded in March. The high leading index growth rate is suggesting that the recovery in primary metals activity should hold firm and possibly gain further traction. The metals price leading index declined for the second consecutive month in February, and its growth rate continued to ease from the record highs reached in 2009. The growth rate is still relatively high and is indicating metal prices should continue to grow, however, at a slower pace than last year.

The primary aluminum and the aluminum mill products indexes are suspended because of discontinued availability of industry-specific historical data. The USGS will continue to calculate the steel and copper composite indexes.

The **primary metals leading index** increased 2.4% in March to 144.2 from a revised 140.8 in February. The index's 6-month smoothed growth rate, a compound annual rate that measures the near-term trend, rose to 17.4% from a revised 14.7% in February. A growth rate above +1.0% is usually a sign of an upward near-term trend for future metals activity, while a growth rate below -1.0% indicates a downward trend. For an explanation of these indexes and a definition of the primary metals industry, [see page 10](#).

All four of the index's available components increased in March. The stock price index combining construction and farm machinery companies and industrial machinery companies rose in March and contributed 1.4 percentage points to the overall increase in the leading index. The Institute for Supply Management's PMI jumped to its highest level since July 2004 and contributed 0.7 percentage points to the leading index. A slightly longer average workweek in primary metals establishments in March added another 0.2 percentage points. The slight increase in the JOC-USGS metals price leading index growth rate rounded to zero. The primary metals leading index will likely be revised next month when the remaining four components become available.

The primary metals leading index growth rate is indicating that the recovery in metals industry activity growth will likely continue. The economic climate in the United States appears strong enough to support healthy domestic metals demand. The metals demand of emerging economies for expanding infrastructure and for manufactured goods will also likely bolster U.S. primary metals activity growth in the near term.

The **steel leading index** increased 0.2% in February, the latest month for which it is available, to 107.5 from 107.3 in January. Its 6-month smoothed growth rate slipped to 8.5% from a revised 9.0% in January. Movement among the steel indicators was mixed in February. The soaring steel scrap price growth rate and a pickup in the inflation-adjusted M2 money supply growth rate made the largest positive contributions to the net increase in the leading index. A slip in the S&P stock index for steel companies offset some of the gains in those indicators. The steel leading index growth rate is still high, indicating that the recovery in U.S. steel industry activity is likely to continue in the near term.

The **copper leading index** increased 0.7% in February to 120.5 from a revised 119.7 in January, but its 6-month smoothed growth rate barely changed, moving to 12.1% from a revised 12.4%. Most of its components posted gains. Longer average weekly hours in nonferrous metals except aluminum manufacturing establishments and new orders for nonferrous metal products made the largest positive contributions to the leading index. A drop in S&P stock price index for building materials companies made the only sizable negative contribution. The copper leading index growth rate continues to indicate a recovery in copper industry activity in the near term.

Metal Prices Still on the Path for Growth

The **metals price leading index** decreased 1.2% to 115.1 in February, the latest month for which it is available, from a revised 116.5 in January. Its 6-month smoothed growth rate

stepped down to 11.6% in February from a revised 17.9% in January. The growth rate of the trade-weighted average exchange value of other major currencies against the U.S. dollar declined for the fourth consecutive month, after nearly a year of increases. It contributed -1.0 percentage points to the net decrease in the leading index. The growth rate of the Organization for Economic Cooperation and Development (OECD) Total Leading Index decreased slightly in February, but held the leading index down -0.5 percentage points. The contribution from a tighter yield spread between the U.S. 10-year Treasury Note and the federal funds rate rounded to -0.1 percentage points. In contrast, a surge in the growth rate of the inflation-adjusted value of new orders for U.S. nonferrous metal products made the only positive contribution, 0.3 percentage points, to the leading index. The metals price leading index signals major changes in the growth

rate of nonferrous metals prices an average of 8 months in advance.

The growth rate of the inflation-adjusted value of U.S. nonferrous metal products inventories, which is an indicator of supply, increased in February. However, the inventory growth rate is still relatively deep in negative territory. Low inventories and the high metals price leading index growth rate suggest that metal prices could continue to grow modestly in the near term.

The business cycle and inventories are only two factors in metal price determination. Other factors that affect prices include changes in metals production, speculation, strategic stockpiling, foreign exchange rates, geopolitical instability, and production costs.

Note: The components of the Leading Index of Metal Prices are the spread between the U.S. 10-year Treasury Note and the federal funds rate, and the 6-month smoothed growth rates of the deflated value of new orders for nonferrous metal products, the Organization for Economic Cooperation and Development (OECD) Total Leading Index, and the reciprocal of the trade-weighted average exchange value of the U.S. dollar against other major currencies. The Metal Industry Indicators (MII) Nonferrous Metals Price Index measures changes in end-of-the-month prices for primary aluminum, copper, lead, and zinc traded on the London Metal Exchange (LME). The steel scrap price used is the price of No. 1 heavy melting. Inventories consist of the deflated value of finished goods, work in progress, and raw materials for U.S.-produced nonferrous metal products (NAICS 3313, 3314, & 335929). Six-month smoothed growth rates are based on the ratio of the current month's index or price to its average over the preceding 12 months, expressed at a compound annual rate.

CHART 6.
COPPER: LEADING AND COINCIDENT INDEXES, 1988-2010

CHART 7.
COPPER: LEADING AND COINCIDENT GROWTH RATES, 1988-2010

Explanation

Each month, the U.S. Geological Survey tracks the effects of the business cycle on five U.S. metal industries by calculating and publishing composite indexes of leading and coincident indicators. Wesley Mitchell and Arthur Burns originated the cyclical-indicators approach for the economy as a whole at the National Bureau of Economic Research in the mid-1930s. Over subsequent decades this approach was developed and refined, mostly at the National Bureau, under the leadership of Geoffrey H. Moore.¹

A business cycle can briefly be described as growth in the level of economic activity followed by a decline succeeded by further growth. These alternating periods of growth and decline do not occur at regular intervals. Composite indexes, however, can help determine when highs and lows in the cycle might occur. A composite index combines cyclical indicators of diverse economic activity into one index, giving decision makers and economists a single measure of how changes in the business cycle are affecting economic activity.

The indicators in the metal industry leading indexes historically give signals several months in advance of major changes in a coincident index, a measure of current metal industry activity. Indicators that make up the leading indexes are, for the most part, measures of anticipations or new commitments to various economic activities that can affect the metal industries in the months ahead.

Composite coincident indexes for the metal industries consist of indicators for production, shipments, and total employee hours worked. As such, the coincident indexes can be regarded as measures of the economic health of the metal industries.

The metal industry coincident indexes reflect industry activity classified by the U.S. Standard Industrial Classification (SIC) and the North American Industry Classification System (NAICS). Of the five metal industries, primary metals (NAICS 331) is the broadest, containing 25 different metal processing industries. Steel, aluminum, and copper are specific industries within the primary metals group.

The SIC was the main vehicle used by the U.S. Government and others in reporting industry economic statistics throughout most of the last century. Starting with the 1997 U.S. Economic Census, the U.S. Government began using the NAICS, which classifies economic data for industries in Canada, Mexico, and the United States. In general, metal industry indexes starting in 1997 begin to reflect the NAICS classification, while indexes for earlier years follow the SIC. Hence, composite indexes from 1997 forward are not entirely consistent with those of earlier years.

The largest change to primary metals because of the NAICS deals with other communication and energy wire manufacturing (NAICS 335929). Under NAICS, this manufacturing has been removed from primary metals and added to electrical equipment, appliance, and component manufacturing. Because monthly shipments and new orders for this wire are not available, the USGS is estimating their values from 1997 onward and adding them to the appropriate metal industry indicators and indexes to maintain consistency.

¹Business Cycle Indicators, A monthly report from The Conference Board (March 1996).

There are other small changes to the primary metals industry because of the switch to the NAICS. Coke oven activity not done by steel mills, for example, is removed and alumina refining, a part of industrial inorganic chemical manufacturing under the SIC, is added. Since the historic trends of the composite indexes are not affected by these small changes, the USGS is not making specific adjustments to the indexes for them for the periods before and after 1997.

The metal industry leading indexes turn before their respective coincident indexes an average of 8 months for primary metals and 7 months for steel and copper. The average lead time for the primary aluminum leading index is 6 to 8 months, and the average lead time for the aluminum mill products leading index is 6 months.

The leading index of metal prices, also published in the *Metal Industry Indicators*, is designed to signal changes in a composite index of prices for primary aluminum, copper, lead, and zinc traded on the London Metal Exchange. On average, this leading index indicates significant changes in price growth about 8 months in advance.

The growth rate used in the *Metal Industry Indicators* is a 6-month smoothed growth rate at a compound annual rate, calculated from a moving average. Moving averages smooth fluctuations in data over time so that trends can be observed. The 6-month smoothed growth rate is based upon the ratio of the latest monthly value to the preceding 12-month moving average.

$$\left[\left(\frac{\text{current value}}{\text{preceding 12-month moving average}} \right)^{\frac{12}{6.5}} - 1.0 \right] * 100$$

Because the interval between midpoints of the current month and the preceding 12 months is 6.5 months, the ratio is raised to the 12/6.5 power to derive a compound annual rate.

The growth rates measure the near-term industry trends. They, along with other information about the metal industries and the world economy, are the main tools used to determine the outlook of the industries. A 6-month smoothed growth rate above +1.0% usually means increasing growth; a rate below -1.0% usually means declining growth.

The next update for these indexes is scheduled for release on the World Wide Web at 10:00 a.m. EDT, Friday, May 21. The address for *Metal Industry Indicators* on the World Wide Web is: <http://minerals.usgs.gov/minerals/pubs/mii/>

The *Metal Industry Indicators* is produced at the U.S. Geological Survey by the Minerals Information Team. The report is prepared by Gail James (703-648-4915; e-mail: gjames@usgs.gov) and Ken Beckman (703-648-4916; e-mail: kbeckman@usgs.gov). The former Center for International Business Cycle Research, under the direction of Dr. Geoffrey H. Moore, and the former U.S. Bureau of Mines developed the metal industry leading and coincident indexes in the early 1990s. Customers can send mail concerning the *Metal Industry Indicators* to the following address:
